DOMAINS OF EXTRACELLULAR REGION OF HUMAN PLATELET DERIVED GROWTH FACTOR RECEPTOR POLYPEPTIDES

FIELD OF THE INVENTION

The present invention relates to receptors for growth factors, particularly to human platelet-derived growth factor receptors (hPDGF-R). More particularly, it provides various composite constructs of human platelet-derived growth factor receptors, these constructs retaining ligand binding regions found in the natural extracellular region of the receptors. It also provides recombinant nucleic acids encoding these polypeptides, typically also comprising a promoter for expression, and fusion peptides on the amino or carboxy terminus of the expressed extracellular composite structure. Antibodies are provided which recognize epitopes containing amino acids contained in different domains of the extracellular region. Cells comprising these polypeptides and nucleic acids, and diagnostic uses of these reagents are also provided.

BACKGROUND OF THE INVENTION

Polypeptide growth factors are mitogens that act on cells by specifically binding to receptors located on the cell plasma membrane. The platelet-derived growth factor (PDGF) stimulates a diverse group of biochemical responses, e.g., changes in ion fluxes, activation of various kinases, alteration of cell shape, transcription of various genes, and modulation of enzymatic activities associated with phospholipid metabolism. See, e.g., Bell et al. (1989) "Effects of Platelet Factors on Migration of Cultured Bovine Aortic Endothelial and Smooth Muscle Cells," Circulation Research 65:1057-1065.

Platelet-derived growth factors are found in higher animals, particularly in warm blooded animals, e.g., mammals. In vitro, PDGF is a major polypeptide mitogen in serum for cells of mesenchymal origin such as fibroblasts, smooth muscle cells, and glial cells. In vivo, PDGF does not normally

circulate freely in blood, but is stored in the alpha granules of circulating blood platelets. During blood clotting and platelet adhesion the granules are released, often at sites of injured blood vessels, thereby implicating PDGF in the repair of blood vessels. PDGF may stimulate migration of arterial smooth muscle cells from the medial to the intimal layer of the artery where the muscle cells may proliferate. This is likely to be an early response to injury.

PDGF has also been implicated in wound healing, in atherosclerosis, in myeloproliferative disease, and in stimulating genes associated with cancerous transformation of cells, particularly c-myc and c-fos.

The platelet-derived growth factor is composed of two homologous polypeptide chains; it is a dimer of 16 kilodalton proteins which are disulfide connected. These polypeptides are of two types, the type B chain and the type A chain. Three forms of the growth factor dimer are found corresponding to a homodimer of two type A chains, a homodimer of two type B chains, and a heterodimer of the type A chain with the type B chain. Each of these three different combinations is referred to as a PDGF isoform. See, for a review on PDGF, Ross et al. (1986) "The Biology of Platelet-Derived Growth Factor," Cell 46:155-169. The growth factor sequences from mouse and human are highly homologous.

The PDGF acts by binding to the platelet-derived growth factor receptor (PDGF-R). The receptor is typically found on cells of mesenchymal origin. The functional receptor acts while in a form comprising of two transmembrane glycoproteins, each of which is about 180 kilodaltons. Two different polypeptides have been isolated, a type B receptor polypeptide and a type A receptor polypeptide.

A sequence of a type B receptor polypeptide of the mouse platelet-derived growth factor receptor polypeptide is published in Yarden et al. (1986) Nature 323:226-232. A sequence of an type A human platelet-derived growth factor receptor (hPDGF-R) polypeptide is disclosed in Matsui et al. (1989) Science 243: 800-803.

These PDGF receptors usually have three major identifiable regions. The first is a transmembrane region (TM) which spans the plasma membrane once, separating the regions of the receptor exterior to the cell from the regions interior to the cell. The second region is an extracellular region (XR) which contains the domains that bind the polypeptide growth factor (i.e., the ligand binding domains). The third is an intracellular region (IR) which possesses a tyrosine kinase activity. This tyrosine kinase domain is notable in having an insert of about 100 amino acids, as compared with most other receptor tyrosine kinase domains which are contiguous or have shorter insert segments.

The complete sequences of the human type B and human type A receptor polypeptides are reported elsewhere, e.g., U.S.S.N. 07/309,322, which is hereby incorporated herein by reference. However, for many purposes, a smaller or less than full length functional protein would be desired. For example, smaller molecules may be more easily targeted to areas of compromised circulation, or present fewer epitopes or extraneous domains unrelated to various activities of interest. Functional analogues with a slightly modified spectrum of activity, or different specificity would be very useful.

Thus, the use of new composite constructs exhibiting biological activity in common with platelet-derived growth factor receptor polypeptides will have substantial use as research reagents, diagnostic reagents, and therapeutic reagents. In particular, the identification of important polypeptide features in the extracellular region of the platelet-derived growth factor receptor polypeptides will allow substitutions and deletions of particular features of the domains. Moreover, use of an in vitro assay system provides the ability to test cytotoxic or membrane disruptive compounds.

SUMMARY OF THE INVENTION

In accordance with the present invention, defined constructs of modified human platelet-derived growth factor receptor polypeptides are provided. Extracellular region domain structures are identified and modifications and combinatorial rearrangements of the receptor segments are furnished. Both cell bound and soluble forms of modified segments are made available, as are methods for assays using them, thereby allowing for screening of ligand analogues.

The present invention provides a platelet-derived growth factor receptor (hPDGF-R) fragment of between about 8 and 400 amino acids comprising one or more platelet-derived growth factor (PDGF) ligand binding regions (LBR's) from extracellular domains D1, D2, or D3, wherein the fragment binds a platelet-derived growth factor ligand. Generally, the fragment will exhibit a binding affinity of about 5 nM or better and will have a sequence of at least about 6 or 8 contiguous amino acids, preferably at least about 15 or more contiguous amino acids from a domain D3 intra-cysteine region. The fragment will often lack a transmembrane region. In other embodiments, the fragment is soluble, is substantially pure, or has at least one ligand binding region derived from a domain D3. The fragment may be derived from a type B, or from a type A PDGF-R LBR fragment, e.g., from Table 1 or Table 2. In particular embodiments, the fragment is selected from the group of formulae consisting of:

a) Xa-Dm-Xc;
b) Xa-Dm-X1-Dn-Xc;
c) Xa-Dm-X1-Dn-X2-Dp-Xc; and
d) Xa-Dm-X1-Dn-X2-Dp-X3-Dq-Xc;
e) Xa-Dm-X1-Dn-X2-Dp-X3-Dq-X4-Dr-Xc;

where the fragment is not D1-D2-D3-D4-D5;

each of Xa, X1, X2, X3, and Xc is, if present, a polypeptide segment lacking a D domain; and

each of Dm, Dn, Dp, and Dq is, independently of one another, selected from the group consisting of D1, D2, D3, D4, and D5. Preferred fragments are selected from the group consisting of:

a) D1-D2-D3 or D3-D4-D5; and

b) D1-D2-D3-D4 or D2-D3-D4-D5.

The present invention also embraces a soluble human platelet-derived growth factor receptor (hPDGF-R) fragment of between about 10 and 350 amino acids comprising at least one platelet-derived growth factor (PDGF) ligand binding region (LBR) from a domain D3, wherein the fragment specifically binds to a platelet-derived growth factor ligand. Usually the fragment comprises a sequence of at least about 15 contiguous amino acids from the intra-cysteine portion of domain D3 and has a binding affinity of better than about 5 nM. Other useful fragment embodiments will be soluble, substantially pure, or a type B or type A PDGF-R LBR, e.g., from Table 1 or Table 2.

The invention also includes nucleic acid sequences, including those encoding the above described polypeptide fragments. Often the nucleic acid sequences incorporate a promoter, generally operably linked to the sequence encoding the fragments.

Cells comprising the nucleic acids or peptides of the invention are also embraced. In particular cell embodiments, the cell will be a mammalian cell, and often will contain both a nucleic acid and a protein expression product of the nucleic acid.

The compositions described above provide antibodies which recognize an epitope of a described PDGF-R fragment, but not a natural PDGF-R epitope. The antibody will often be a monoclonal antibody.

The present invention also provides a method for measuring the PDGF receptor binding activity of a biological sample comprising the steps of:

a) contacting an aliquot of a sample to a PDGF ligand in the presence of a described PDGF-R fragment in a first analysis;

b) contacting an aliquot of the sample to a PDGF ligand in the absence of the PDGF-R fragment in a second analysis; and

c) comparing the amount of binding in the two analyses.

In some instances, the PDGF-R fragment is attached to a cell, or a solid substrate, e.g., a microtiter dish.

The invention also embraces a method for measuring the PDGF ligand content of a biological sample comprising the steps of:

a) contacting an aliquot of the sample to a ligand binding region (LBR) in the presence of a described PDGF-R fragment in a first analysis;

b) contacting an aliquot of the sample to a LBR in the absence of the PDGF-R fragment in a second analysis; and

c) comparing the amount of binding in the two analyses.

In some embodiments, the contacting steps are performed simultaneously.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 illustrates a strategy for oligonucleotide directed in vitro deletion mutagenesis of soluble hPDGF-R extracellular domains. Many of these constructs will be soluble peptides, or can be modified to be such.

The abbreviations used are:

PR = PDGF-R; intact
P = PDGF-R; extracellular region
TM = transmembrane
K = kinase
S = signal sequence

Fig. 2 illustrates the structure of a plasmid derived form pcDL-Sα296 used for expressing various deletion polypeptides.

Fig. 3 illustrates the structure of a plasmid pBJΔ derived from pcDLα296. See Takabe et al. (1988) Mol. Cell. Biol. 8:466-472.

1. The pcDL-SRα296 is cut with XhoI.
2. A polylinker (XhoI-XbaI-SfiI-NotI-EcoRI-EcoRV-HindIII-ClaI-SalI) is inserted into the XhoI cut vector.
3. SalI is compatible with the XhoI site; and generates both a SalI and an XhoI site.
4. The SV40 16s splice junction is no longer present.

Fig. 4 illustrates the inhibition of receptor phosphorylation by a human type B PDGF receptor polypeptide. Labeling with a reagent which binds to phosphorylated tyrosine shows that phosphorylation activity is decreased in the presence of the receptor polypeptide fragment.

I. General Description

A. Platelet-derived growth factor receptor (PDGF-R)

The human platelet-derived growth factor receptor (hPDGF-R) typically comprises two polypeptides. These polypeptides, which may be identical or only slightly different, associate during the functional activities of ligand binding and transducing of the ligand binding signal into the cell.

The platelet-derived growth factor receptor was identified as having a major component of an approximately 180 kilodalton protein which is glycosylated. This glycoprotein was identified as a platelet-derived growth factor receptor polypeptide. Primary structures of two homologous forms of polypeptides have been reported. A type B receptor nucleic acid and its corresponding polypeptide sequence from mouse are reported in Yarden et al. (1986) Nature 323: 226-232; and a homologous genetic sequence has been isolated from humans. See U.S.S.N. 07/309,322. A human type A receptor sequence is reported in Matsui et al. (1989) Science 243: 800-803. Although the two different forms of the receptor polypeptides are homologous, they are encoded by two separate genes.

The functional receptor apparently involves a dimer of these polypeptides, either homodimers of the type B receptor polypeptide or of the type A receptor polypeptide, or a heterodimer of the type B receptor polypeptide with an type A receptor polypeptide. The specificity of binding of each of these forms of the receptor is different for each of the different forms of platelet-derived growth factor (PDGF), the AA, BB, or AB forms (from either mouse or human, or presumably other mammals).

The PDGF-R is a member of a family of related receptors. See, e.g., Yarden et al. supra. Each of these receptor polypeptides has a hydrophobic membrane spanning region (TM for transmembrane), a large extracellular region (XR) with regularly spaced cystine residues, and a cytoplasmic intracellular region (IR) having intracellular tyrosine kinase activity. The XR of the PDGF-R has a predicted structure containing 5 β-strand-rich immunoglobulin (Ig)-like domains.

Each of these Ig-like domains consists of about 100 amino acids, ranging more specifically from about 88 to about 114 amino acids, and, except for the fourth domain, contains regularly spaced cysteine residues. Many of the structural features of the various growth factor receptors are homologous, including the mouse and human versions of the PDGF-R. Thus, many of the structural features defined herein are shared with other related proteins. However, in most cases, the functional relationship to particular structural features is unknown.

The intracellular region (IR) is that segment of the PDGF-R which is carboxy proximal of the transmembrane (TM) segment. The intracellular region is characterized, in part, by the presence of a split tyrosine kinase structural domain. In the human type B receptor polypeptide, the tyrosine kinase domain is about 244 amino acids with an insert of about 104 amino acids. See Table 1. In the human type A receptor polypeptide, the domain is about 244 amino acids long with a kinase insert of about 103 amino acids. See Table 2. Functionally, this domain is defined, in part, by its tyrosine kinase activity, typically modulated by ligand binding to binding sites found in the extracellular region, and appears to function in a dimer state. The substrate for phosphorylation includes various tyrosine residues on the accompanying receptor polypeptide chain, and other proteins which associate with the receptor. The tyrosine kinase domain is also defined, in part, by its homology to similar domains in other tyrosine kinase activity containing proteins. See, e.g., Yarden et al. (1986) Nature 323:226-232. Each IR segment of the dimerized receptor complex appears to phosphorylate specific tyrosine residues on the other polypeptide chain.

Each transmembrane segment of the human receptor polypeptides is about 24 or 25 amino acids long and is characterized by hydrophobic amino acid residues. These segments have sequences characteristic of membrane spanning segments. In the human type B receptor polypeptide the transmembrane region appears about 25 amino acids long extending from about val(500) to trp(524), while in the human type A receptor polypeptide, the transmembrane segment appears

to be about 24 amino acids extending from about leu(502) to trp(526). See, e.g., Claesson-Welsh et al. (1989) Proc. Nat'l Acad. Sci. USA, 86:4917-4921.

A polypeptide or nucleic acid is a "human" sequence if it is derived from, or originated in part from, a natural human source. For example, proteins derived from human cells, or originally encoded by a human genetic sequence, will be human proteins. A sequence is also human if it is selected on the basis of its high similarity to a sequence found in a natural human sample, or is derived therefrom.

A fusion polypeptide or nucleic acid is a molecule which results from the fusion of segments from sequences which are not naturally in continuity with one another. Thus, a chimeric protein or nucleic acid is a fusion molecule. A heterologous protein is a protein originating from a different source.

B. Physiological Functions

The PDGF-R appears to have at least four major different biological functions. The first is the binding of ligands, usually the PDGF mitogenic proteins or their analogues. These ligands and analogues may also serve as either agonists or antagonists. The ligand binding sites, made up of ligand binding regions (LBR's), are localized in the extracellular region (XR). The functional receptor transduces a signal in response to ligand binding, and the resulting response is a ligand modulated activity. As the likely ligand is a PDGF, or an analogue, the signal will ordinarily be PDGF modulated.

A second biological activity relates to the tyrosine kinase enzymatic activity. This activity is typically activated intracellularly in response to ligand binding. However, since these receptors apparently function in a dimeric state, the interchain binding interactions may be considered a third biological activity which may be mediated by blocking agents. Blocking or interference with the dimerization interactions may be mediated by receptor protein fragments, particularly in the functional ligand binding or tyrosine

kinase activities. Thus, the introduction of analogues of the receptor domains to natural or other receptor polypeptides may serve as an additional means to affect PDGF mediation of ligand mediated activities.

The fourth function of the PDGF receptor is as a binding substrate for other proteins, e.g., the PI3 kinase. In particular, the PDGF receptor is phosphorylated at various positions in response to ligand binding or other events. This binding interaction activates an enzymatic activity on the part of the binding protein which activates further cellular or metabolic responses.

The term "ligand" refers to the molecules, usually members of the platelet-derived growth factor family, that are bound by the ligand binding regions (LBR's). The binding regions are typically found in the XR. Also, a ligand is a molecule that serves either as the natural ligand to which the receptor binds, or a functional analogue of a ligand. The analogue may serve as an agonist or antagonist. Typically ligands will be molecules which share structural features of natural PDGF, e.g., polypeptides having similar amino acid sequences or other molecules sharing molecular features with a ligand. The determination of whether a molecule serves as a ligand depends upon the measurement of a parameter or response which changes upon binding of that ligand, such as dimerization or tyrosine kinase activity. See, e.g., Gilman et al. (eds) (1990) Goodman and Gilman's: The Pharmacological Bases of Therapeutics, 8th Ed., Pergamon Press, which is incorporated herein by reference.

The receptor has ligand binding regions (LBR), or regions which are important in determining both affinity and specificity of binding of ligand, e.g., PDGF and its analogues. The ligand binding regions determine the binding interactions between the receptors and ligand. Typically, these regions are those contact points between the ligand molecule and the receptor. These molecular interactions can be determined by crystallographic techniques, or by testing which regions of the receptor are important in ligand interaction. Various segments of the extracellular region of the PDGF receptor make up the

ligand binding regions, while other segments form structural segments which spatially orient the LBR's in proper arrangement to properly bind the ligands.

Generally, the fragment will have a sequence of at least about 6 contiguous amino acids, usually at least about 8 contiguous amino acids, more usually at least about 10 contiguous amino acids, preferably at least about 13 contiguous amino acids, and more preferably at least about 15 or more contiguous amino acids. Usually, the LBR's will be located within the intra-cysteine (or equivalent) residues of each Ig-like domain, e.g., domains D1, D2, D3, D4, and D5. They will be preferably derived from D3 sequences, but D1 and D2 derived sequences will also be common. Occasionally, sequences from D4, D5, or other proteins will provide LBR function.

The extra-cysteine (or equivalent) regions provide structural functions, as will inter-domain spacer segments. The intra-cysteine portions, or segments, are indicated in Tables 4 and 5, and comprise the segments designated C, C', C", D, and E, along with portions of the B and F segments, as indicated. The extra-cysteine residues comprise the segments designated A and G, and portions of B and F.

The ligand binding regions as defined, in part, by the importance of their presence, or their effect on the affinity of PDGF ligand binding. The natural, native full length PDGF-R binds with a K_d of about 0.2 mM. See, e.g., Duan et al. (1991) J. Biol. Chem. 266:413-418, which is hereby incorporated herein by reference. An LBR is a segment of polypeptide whose presence significantly affects ligand binding, generally by at least about a factor of two, usually by at least about a factor of four, more usually by at least a factor of about eight, and preferably by at least about a factor of twelve or more. A fragment of this invention which binds to the PDGF ligand will generally bind with a K_d of less than about 10 μM, more generally less than about 1 μM, usually less than about 0.1 μM, more usually less than about 10 nM, preferably less than about 1 nM, and more preferably less than about 0.5 nM.

An epitope is an antigenic determinant which potentially or actually has elicited an antibody response. It may also refer to a structural feature which is defined by an antibody binding region, or its equivalent. An epitope need not necessarily be immunogenic, but will serve as a binding site for an antibody molecule or its equivalent.

II. Polypeptides

Table 1 discloses the sequence of one allele of a type B human platelet-derived growth factor receptor polypeptide. Both a nucleic acid sequence and its corresponding protein sequence are provided. The nucleic acid sequence corresponds to Seq. ID No. 1. The amino acid sequence corresponds to Seq. ID No. 2. A homologous mouse sequence was reported in Yarden et al. (1988) Nature 323:226-232. The sequence of a mouse PDGF receptor polypeptide also exhibits structural features in common with the regions, the domains, and the β-strand segments of the human receptor polypeptides. The mouse polypeptides, and those from other related receptors, will serve as a source of similar domains, homologous β-strand segments, and inter-segment sequences, and sequences of homology for general replacement or substitutions.

Table 2 discloses the sequence of an allele of an type A human platelet-derived growth factor receptor polypeptide. Both a nucleic acid sequence and its corresponding protein sequence are provided. The nucleic acid sequence corresponds to Seq. ID No. 5. The amino acid sequence corresponds to Seq. ID No. 4. Another human type A allele sequence is reported in Matsui et al. (1989) Science 243:800-803.

A polypeptide or nucleic acid is substantially pure, or substantially purified, when it comprises at least about 30% of the respective polymer in a composition, typically at least about 50%, more typically at least about 70%, usually at least about 80%, more usually at least about 90%, preferably at least about 95%, and more preferably about 98% or more.

The soluble fragments of the extracellular region will generally be less than about 400 amino acids, usually less than about 350 amino acids, more usually less than about 300 amino acids, typically less than about 200 amino acids, and preferably less than about 150 amino acids.

A. D Domains

Based on a number of observations, the extracellular region (XR) of these PDGF receptor polypeptides comprises 5 immunoglobulin-like domains. First, the amino acid sequence contains 5 segments characteristic of Ig-like domain structures, each of the segments having an appropriate size for an immunoglobulin domain. Each segment, except for the fourth, has characteristically spaced cysteine residues that are a diagnostic feature of an immunoglobulin-like domain. The receptor polypeptide sequence displays other features of immunoglobulin-like domain structure, e.g., the presence of characteristically positioned tryptophan and tyrosine residues. Direct sequence comparisons of segments of the receptor polypeptides with corresponding segments of true immunoglobulin domains shows a statistically significant similarity between PDGF receptor polypeptide domains and immunoglobulin domains. See, e.g., Williams (1989) Science 243: 1564-1570. The argument that the receptor polypeptide domains assume the folding pattern of immunoglobulin domains can be strengthened by examining the predicted secondary structure of the receptor polypeptides.

When a homology mapping analysis is performed, the PDGF receptor polypeptide shows five Ig-like domains in the extracellular region, each domain showing statistically significant homology to defined Ig-like domains. See, e.g., Williams and Barclay (1988) Ann. Rev. Immunol. Biochem. 6: 381-

405. Regions of homology will show significant sequence homology to particular Ig-like domains, and exhibit particular secondary and tertiary structural motifs characteristic of Ig-like domains. The domain structures will preferably be those segments with boundaries which approximately match the boundaries of the domain structures. The boundaries will preferably match within about 9 amino acids, typically within about 7 amino acids, more typically within about 5 amino acids, usually within about 3 amino acids, and more usually within 1 amino acid. See, e.g., Cantor and Schimmel (1980) Biophysical Chemistry, Vols I-III, Freeman and Co., San Francisco; Creighton (1984) Proteins: Structure and Molecular Properties, Freeman and Co., New York; and Watson et al. (1987) The Molecular Biology of the Gene, Vols 1 and 2, Benjamin, Menlo Park, California; each of which is hereby incorporated herein by reference.

The sequences of the human type B and the human type A receptor polypeptides can be analyzed to predict their beta strand topology. Combining a Fourier analysis of hydrophobic sequence pattern and a Garnier-Robson algorithm, see, e.g., Garnier et al. (1978) J. Mol. Biol. 120: 97, with a turn predictor program, as reported in Cohen et al. (1986) Biochemistry 25: 266, produces a characteristic structural pattern. This pattern exhibits consensus β-strand segments in each domain when analysed as described.

The first two Ig-like domains of the PDGF receptor polypeptides, D1 and D2, have about seven β-strand segments, designated the A, B, C, D, E, F, and G segments, as listed from amino proximal to carboxy proximal direction. The third, fourth and fifth Ig-like domains, D3, D4 and D5, are long enough to include an extra β-strand segment, designated C'. The fifth domain, D5, most closely resembles a variable heavy chain domain in length. The type B receptor polypeptide D5 further comprises an additional β-strand segment designated C". These features and designations are based partly on the homology of segments between domains and segments in the type B and type A hPDGF-R polypeptides, and with the mouse type B PDGF receptor polypeptide, and also based upon homology to other Ig-

like segments found on other proteins, particularly other growth factor receptor proteins. The csf-1 receptor and c-kit proto-oncogene have similar Ig-like domain organizations. See, e.g., Williams (1989) Science 243:1564-1570.

The domain structure is based, in part, upon features common to Ig-like domains found in other proteins, including related receptors. See, e.g., Ullrich and Schlessinger (1990) Cell 61:203-212; and Yarden and Ullrich (1988) Ann. Rev. Biochem. 57:443-78. The domain boundaries for the two alleles disclosed herein are identified below, but different alleles may have slightly different positions for the boundaries. See Table 14.

The Ig-like domains (D domains) are characterized by the regularity of spacing of cysteine residues in the extracellular region. These five D domains, each about 100 amino acids in length, have β-sheet rich structures, resembling immunoglobulin variable or constant regions. See, Williams (1989) Science 243:1964-1570. The natural XR domains are numbered from the amino proximal domain D1, in order, through D5, at the carboxy proximal end of the XR.

The exon structure of the mouse type B PDGF receptor polypeptide gene also matches this domain structure with reasonable fidelity. The correlation between the intron-exon structure and functional units further supports the hypothesis that the boundaries define functional units of the polypeptide. See, e.g., Williams and Barclay (1988) Ann. Rev. Immunol. Biochem. 6:381-405. The boundaries for each of these segments are indicated below for the two alleles disclosed herein, and similar boundaries will be found in other alleles at locations of sequence and functional homology.

The amino-proximal Ig-like domain of the human platelet-derived growth factor receptor polypeptides is designated D1. The D1 domain extends from about leu(1) to pro(91) in the type B receptor polypeptide, and from about gln(1) to pro(101) in the type A receptor polypeptide. See Table 14. The D1 domain apparently has about seven β-sheet segments.

G	glu (90) - val (98)	ile (178) - lys (186)	met (279) - his (287)	thr (383) - pro (391)	glu (490) - pro (496)

The next Ig-like domain, in the carboxy proximal direction of natural human platelet-derived growth factor receptor polypeptides, is designated D2. The D2 domain extends from about thr(92) to ser(181) in the type B receptor polypeptide, and from about asp(102) to ser(189) in the type A receptor polypeptide. The D2 domain apparently also has about seven β-sheet strands designated A, B, C, D, E, F, and G.

The third Ig-like domain found on natural human PDGF receptor polypeptides is designated D3. The D3 domain extends from about ile(182) to gly(282) in the type B receptor polypeptide, and from about glu(190) to gly(290) in the type A receptor polypeptide. The D3 domain apparently has about eight β-sheet strands designated A, B, C, C', D, E, F, and G.

The fourth Ig-like domain found in the natural human PDGF receptor polypeptides is designated D4. The D4 domain extends from about tyr(283) to pro(384) in the type B receptor polypeptide, and from about phe(291) to pro(391) in the type A receptor polypeptide. The D4 domain apparently has about eight β-sheet strands. Note that the D4 domains lack the characteristic cysteine residues, which correspond to val(306) and met(364) in the type B sequence shown, and to val(313) and ile(371) in the type A sequence shown.

The fifth Ig-like domain is designated D5. The D5 domain extends from about val(385) to lys(499) in the type B receptor polypeptide, and from about ser(392) to glu(501) in the type A receptor polypeptide. The D5 of the type B receptor polypeptide has about nine putative β-sheet strand segments designated A, B, C, C', C", D, E, F, and G, while the type A receptor polypeptide has only about eight β-strand segments, lacking a C" segment.

The approximate boundaries of the domains and β-strand segments are listed in Table 14. The apparent alignments of the segments are illustrated in Tables 4 and 5. Other alleles of the receptor polypeptides may also be analyzed by either homology or the structural analysis as described above.

```

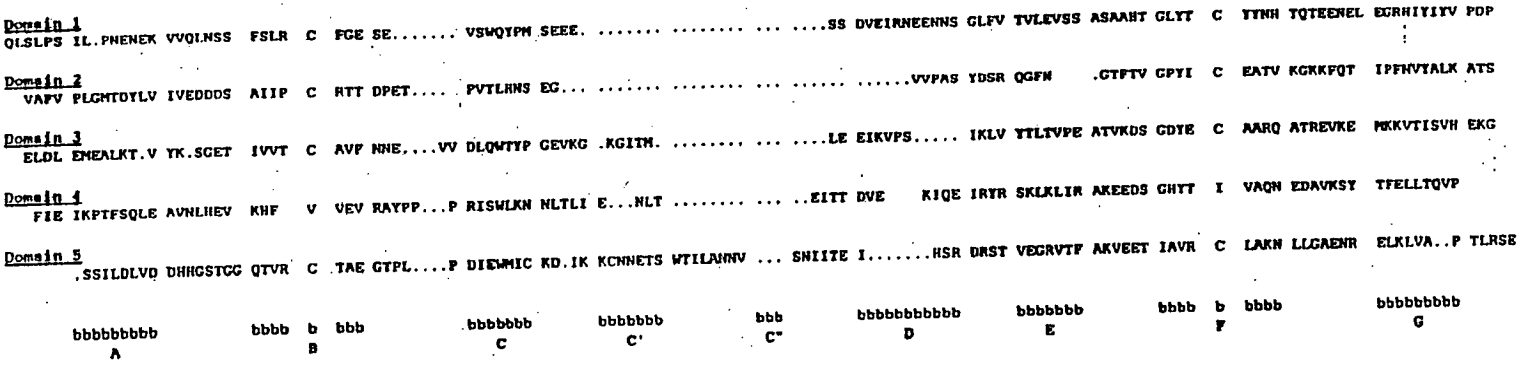
an A-type receptor polypeptide amino acid sequence, with β-strand segment alignment

TABLE 5



The prototypical D1 domains are those sequences of the human type B receptor polypeptide and the human type A receptor polypeptide, as described. However, compatible amino acid substitutions, insertions, and deletions which preserve the desired ligand binding functions can be made. The function will usually be preserved by retaining the LBR segments in the correct orientation by use of appropriate structured segments. Conservative substitutions typically include substitutions within the following groups: glycine, alanine; valine, isoleucine, leucine; aspartic acid, glutamic acid; asparagine, glutamine; serine, threonine; lysine, arginine; and phenylalanine, tyrosine. Substitution or exchange of β-sheet segments or sequences intermediate the segments from different domains may be performed, including between type B and A receptor polypeptides, or between different domains of another related receptor polypeptide. Segments outside the prototypical cysteines within β-segments B and F (but val(306) and met(364) in the type B D4, and val(313) and ile(371) in the type A D4) will be usually less critical than the sequences between those residues, e.g., the C, C', C", D; and E β-strand segments. Also, segments homologous to these disclosed segments may be substituted, including those with compatible amino acid substitutions, insertions, and deletions. Sources of similar domains and segments include related receptor polypeptides from human or other mammalian species. Non-mammalian receptor polypeptides may also exhibit significant homology and serve as sources for similar segments. Other Ig-like domains and segments may also be substituted.

The present invention embraces polypeptides which exhibit homology to the disclosed and described segments and domains. It embraces segments comprising contiguous amino acids of the sequences disclosed, typically at least about 8 contiguous amino acids, more typically at least about 11 contiguous amino acids, usually at least about 14 contiguous amino acids, more usually at least about 17 contiguous amino acids, and preferably at least about 21 or more contiguous amino acids. Constructs retaining the LBR segments are most valuable. The invention also includes modifications of those

sequences, including insertions, deletions, and substitutions with other amino acids. Glycosylation modifications, either changed, increased amounts, or decreased amounts, as well as other sequence modifications are envisioned. Thus, the modified proteins comprising these amino acid sequences, e.g., analogues, will usually be substantially equivalent to these proteins in either function or structure.

The β-sheet strands may be slightly enlarged or shortened by respective insertions or deletions in the polypeptide sequence. Thus, certain embodiments will have a slightly enlarged or shortened particular domain by adding or deleting particular sequences of β-sheet strands or their inter-strand sequences. Segments may be inserted or deleted which conform to the structural requirements of retaining the proper intra- and inter-domain interactions. In particular, changes which interrupt the secondary and tertiary structure of the protein will be disfavored. See, e.g., Cantor and Schimmel (1990) and Creighton (1984). In addition, amino acids or segments may be inserted or deleted in the regions outside of the β-sheet strands and between domains. Typically the substitutions will be of amino acids having similar properties, and additions or deletions would preferably be selected among those which retain receptor biological functions, e.g., ligand binding.

The sequence of a β-sheet segment will typically not differ from a sequence from a human type B polypeptide or a human type A polypeptide by greater than about 50%, more typically less than about 39%, usually less than about 29%, and more usually less than about 20%. Comparable similarities over each of the non-β-sheet strands of each domain will be preferred.

The boundaries between domains are defined, in part, by the definitions for domains in the Ig-like domains. Examples of similar domains are found in immunoglobulin and growth factor receptor polypeptides. The domain boundaries between D1 and D2; D2 and D3; D3 and D4; and D4 and D5 correspond approximately to exon locations, further supporting the proposal that the domain structures correspond to

evolutionary and functional units. See, e.g., Watson et al. (1987) The Molecular Biology of the Gene, vols. 1 and 2, Benjamin, Menlo Park, California.

The D2 domains have similar characteristics to the D1 domains, as shown by the alignments illustrated in Tables 4 and 5. Both domains have β-sheet segments designated A, B, C, D, E, F, and G. The domain 3 segments, or D3, also exhibit homology, but have an additional β-strand segment designated C'. The D4 segments, or D4, have non-cysteine residues at the positions which typically correspond to cysteines in the other domains. In the type B allele shown, the residues are val(306) and met(364), while in the type A allele shown, the residues are val(313) and ile(371). The D4 domains also have β-strand segments designated C'. The domain 5, or D5, have the consensus cysteine residues and the additional C' β-strand segments, and the type B receptor polypeptide has an additional C" β-strand segment.

The present invention provides for various constructs comprising ligand binding constructs, typically comprising substantially intact domains. These constructs will have various uses,e.g., for binding ligands, or substituting for intact receptor polypeptides. For example, each of the separate domains may comprise a separate polypeptide alone, or may be fused to another peptide, such as the TM and IR regions of a receptor polypeptide, e.g., hPDGF-R. See, e.g., Table 6. These individual single domain polypeptides will exhibit specific activity associated with these specific domains, preferably as an agonist or antagonist for ligand binding, preferably with characteristics shared with the intact receptor polypeptide or XR. The domains may also preferably serve as competitive inhibitors of PDGF-R polypeptides, competing with natural PDGF-receptors to bind ligands. The present invention also provides repetitive sequences of a single domain. For example, a D1 domain by itself is provided, a D1-D1 dimer in a single polypeptide is provided, a D1-D1-D1 triplet repeat is also provided. Likewise up to a large number of D1 domains which will exhibit many functions, e.g., immunological properties, characteristic of various natural PDGF-R sequences.

Similar constructs of each of D2, D3, D4, and D5 are provided, along with combinations. See Tables 6, 7, 8, 9 and 10. These will often be soluble fragments of the XR, or may be fused to other polypeptides, including a PDGF-R TM segment, preferably with an IR segment also.

where Y is each of the 625 possible combinations listed in TABLE 6, but not including the combination D1-D2-D3-D4-D5, giving a total of 3124 elements in this table

In addition, the present invention provides similar structures with spacer regions between the domain structures. In particular, the regions corresponding to the intra-cysteine residues of the domains shown in Tables 4 and 5 are useful. For example, a spacer polypeptide may be inserted between adjacent domains or do spaces between the important ligand binding segments, typically found within the intra-cysteine segments described, e.g., the B, C, C', C", D, E, and F β-strand segments. Thus, for example, a polypeptide of the structure D1-X1-D2 is provided where X1 is a spacer segment which is not a D domain. The order of the domains may be reversed, and the invention also provides polypeptides such as D2-D1, or D2-X1-D1. In particular, the non-D domain character of X1 is provided to avoid the peptide D1-X1-D3 from describing, or encompassing, D1-D2-D3.

Another particularly preferred embodiment of the invention is a polypeptide having the described extracellular region domain structure combined with other segments of a human platelet-derived growth factor receptor, particularly the transmembrane segment (TM) and the intracellular region (IR). Thus, the present invention provides for a receptor polypeptide which either has a modified order of the extracellular region domains in the amino to carboxy direction, e.g., a D5-D4-D3-D2-D1-TM-IR polypeptide, or, in some cases reversal of various domains. It also provides for a receptor polypeptide with a deleted intact domain and for a receptor polypeptide having an additional domain added to it. Examples include D1-D2-D3-TM-IR, or D1-D2-D3-D4-TM-IR. In particular, fusions with the XR segments described in Tables 6, 7, 8, 9, and 10 are preferred embodiments.

The modified combinations of the D domains are expected to both simulate and differ from the natural receptor. The modified polypeptide would be expected, in some embodiments, to exhibit a modified binding affinity, e.g., higher or lower affinity, or to exhibit a different spectrum of binding to different ligands or ligand analogues. They may also have an altered ligand binding transducing efficiency, or a modified inter-chain association affinity.

The present invention provides the means for determining the minimal structural features necessary to perform various functions of the extracellular region of platelet-derived growth factor receptors, preferably human receptors. Although similar determinations may be performed in mouse or other mammalian species, the human receptor will typically be preferred for diagnostic or therapeutic purposes.

To determine the minimal region necessary for a functional activity, e.g., ligand binding, an assay for that activity is developed. The main receptor functions, as indicated above, include ligand binding, tyrosine kinase activity, and receptor dimerization. Simple and quick assays for each of these molecular functions may be developed. Ligand binding assays are described, e.g., in Gronwald et al. (1988) Proc. Nat'l Acad. Sci. USA 85:3435-3439; Heldin et al. (1988) EMBO J. 7:1387-1393; and Escobedo et al. (1988) Science 240:1532-1534. Receptor dimerization assays are described, e.g., in Yarden and Schlessinger (1987) Biochemistry 26:1434-1442 and 1443-1451.

As an alternative means for determining sites which interact with specific other proteins, physical structure determination, e.g., x-ray crystallography or 2 dimensional NMR techniques, will provide guidance as to which amino acid residues form the molecular contact regions. For a detailed description of protein structural determination, see, e.g., Blundell and Johnson (1976) Protein Crystallography, Academic Press, New York, which is hereby incorporated herein by reference.

Ligand binding assays may include binding of labeled ligand or competition assays for binding. Signal transduction may be indirectly assayed by measuring an activity modulated by ligand binding, e.g., tyrosine kinase activity, or some measure of a conformational or other change in receptor structure. For example, an antibody or other binding protein which specifically binds or dissociates from the receptor polypeptide upon ligand binding may be used. Receptor dimerization may be measured by a proximity assay, including a fluorescence quenching or other spectroscopic measurement. Various

proximity assays are known, see, e.g., Ullrich and Schlessinger (1990) Cell 61:203-212; Yarden and Schlessinger (1987) Biochemistry 26:1434-1942 and 1443-1451; each of which is hereby incorporated herein by reference.

Once an assay has been developed, various combinations of domain or other segments, e.g., LBR's, can be tested for affecting that activity. A competitive inhibition assay will detect those constructs which can bind the ligand. The first domain structures to try will ordinarily be the individual domains, either alone or linked to chimeric proteins or the TM-IR segment of the receptor. Various alleles, modifications to the individual domains, or related chimeric domains would be tested. Both deletion and chimeric proteins will be constructed.

Various combinations of each domain will be constructed and tested to select those which affect the measured activity. Repeats of those domains should be tested, e.g,., D1-D1. If no single domain does affect the function, then various 2 domain constructs, in order, would be tried, e.g., D1-D2-TM-IR, D2-D3-TM-IR, D3-D4-TM-IR, and D4-D5-TM-IR. Selected combinations listed in Tables 6, 7, 8, 9, and 10 will be constructed and tested.

In order to produce soluble forms, it will often be desireable to attach appropriate amino terminal segments, some of which would be expected to be present in the D1 domain or in the precursor form. Correct secretion and processing may be dependent upon various amino proximal features, such as signal sequences, and other features essential for correct targeting and processing. See, e.g., Watson et al. (1987) The Molecular Biology of the Gene, vols. 1 and 2, Benjamin, Menlo Park, California.

When correct domains have been selected which are especially effective in modulating or competing defined functions, a more detailed analysis, to the level of the β-strand segments might be addressed. Various chimeric, deletion, insertion, or substitution constructs of each β-strand or inter-strand segment may be generated and tested, as described above. Each construct could be produced using

methods of standard genetic engineering, especially using synthetic primers. Procedures for using such reagents are described, e.g., in Sambrook, et al. (1989) Molecular Cloning: A Laboratory Manual, vols. 1-3, Cold Spring Harbor Press, and Ausubel et al. (eds.) (1989) Current Protocols in Molecular Biology, Wiley, each of which is hereby incorporated herein by reference.

B. Soluble Forms

In some embodiments, only the extracellular region is provided. Thus, the extracellular region alone, without the transmembrane segment, will often be a soluble polypeptide. It has been demonstrated that the entire extracellular region, separated from, and which lacks a transmembrane region and an intracellular region, still serves as a ligand binding polypeptide. In particular, the soluble polypeptide D1-D2-D3-D4-D5 has been demonstrated to bind various PDGF forms. Although the binding specificity for the PDGF form is dependent, to some extent, on the specific domains included, modifications to the specificity of the ligand binding may be effected by either substituting various different domains or rearranging the domains. Substitution with other homologous segments may also be performed, e.g., substituting an Ig-like domain from an antibody molecule, such as an antibody which binds a platelet-derived growth factor. Alternatively, a domain from a different related growth factor or ligand receptor may be substituted, e.g., from an FGF receptor or another PDGF receptor. The order of the domains may also be modified, e.g., D5-D4-D3-D2-D1.

In particular, the activities which will usually be of greatest importance with the extracellular constructs relate to the binding of the ligand. For example, it has been discovered that domains D4 and D5 are not essential for ligand binding of a soluble extracellular region PDGF-R polypeptide. Of the remaining domains, if domain D3 is separated from domains D1 and D2, the construct D1-D2 binds the ligand only at low affinity, but a D1-D2-D3 construct binds ligand at high affinity.

A typical hPDGF-R nucleic acid sequence encodes a transitory amino terminal hydrophobic sequence, which is usually cleaved during the membrane translocation process. The classical function of a signal sequence is to direct the nascent polypeptide chain to membrane bound ribosomes, thereby leading to membrane translocation or cellular targeting. However, since the signal sequence is typically removed in the translocation process, the signal sequence is usually absent in a mature polypeptide. Often a signal sequence will be attached upstream of a desired soluble peptide of this invention.

Solubility of a polypeptide depends upon the environment and the polypeptide. Many parameters affect polypeptide solubility, including the temperature, the electrolyte environment, the size and molecular characteristics of the polypeptide, and the nature of the solvent. Typically, the temperature at which the polypeptide is used ranges from about 4°C to about 65°C. Usually the temperature at use is greater than about 18°C and more usually greater than about 22°C. For diagnostic purposes, the temperature will usually be about room temperature or warmer, but less than the denaturation temperature of components in the assay. For therapeutic purposes, the temperature will usually be body temperature, typically about 37°C for humans, though under certain situations the temperature may be raised or lowered in situ or in vitro.

The electrolytes will usually approximate in situ physiological conditions, but may be modified to higher or lower ionic strength where advantageous. The actual ions may be modified to conform to standard buffers used in physiological or analytical contexts.

The size and structure of the polypeptide should be in a substantially stable and globular state, and usually not in a denatured state. The polypeptide may be associated with other polypeptides in a quaternary structure, e.g., to confer solubility.

The solvent will usually be a biologically compatible buffer, of a type used for preservation of biological activities, and will usually approximate a physiological

solvent. On some occasions, a detergent will be added, typically a mild non-denaturing one.

Solubility is usually measured in Svedberg units, which are a measure of the sedimentation velocity of a molecule under particular conditions. The determination of the sedimentation velocity was classically performed in an analytical ultracentrifuge, but is typically now performed in a standard ultracentrifuge. See, Freifelder (1982) Physical Biochemistry (2d ed.), W.H. Freeman, and Cantor and Schimmel (1980) Biophysical Chemistry, parts 1-3, W.H. Freeman & Co., San Francisco, each of which is hereby incorporated herein by reference. As a crude determination, a sample containing a "soluble" polypeptide is spun in a standard full sized ultracentrifuge at about 50K rpm for about 10 minutes, and soluble molecules will remain in the supernatant. A soluble particle or polypeptide will typically be less than about 30S, more typically less than about 15S, usually less than about 10S, more usually less than about 6S, and, in particular embodiments, preferably less than about 4S, and more preferably less than about 3S.

This invention provides platelet-derived growth factor polypeptides and proteins having platelet-derived growth factor receptor ligand binding activity. The receptors of the present invention include PDGF receptor amino acid sequences such as those shown in Tables 6, 7, 8, 9, and 10. Also provided are homologous sequences, allelic variations, induced mutants, alternatively expressed variants, and proteins encoded by DNA which hybridize under high stringency conditions to PDGF receptor encoding nucleic acids retrieved from naturally occurring material.

The platelet-derived growth factor receptor peptides of the present invention will exhibit at least about 80% homology with naturally occurring domains of hPDGF receptor sequences in the domains D1, D2, D3, D4, and D5, typically at least about 85% homology with a natural form of a receptor sequence, more typically at least about 90% homology, usually at least about 95% homology, and more usually at least about 97% homology.

Homology, for polypeptides, is typically measured using sequence analysis software, see, e.g., Sequence Analysis Software Package of the Genetics Computer Group, University of Wisconsin Biotechnology Center, 1710 University Avenue, Madison, Wisconsin 53705. Protein analysis software matches similar sequences using measure of homology assigned to various substitutions, deletions, substitutions, and other modifications. Similar, or homologous, substitutions for LBR segments will be made in known sequences, thereby producing new binding molecules having modified affinity or specificity of ligand binding.

Various other software analysis programs can analyze the conformational structure of a polypeptide. Homologous conformation may also be achieved by appropriate insertion, deletion, substitution, or modification of amino acid sequences. Since the conformational structure of the domains and β-strand segments is only partially understood, the present invention also encompasses various modifications to the sequences disclosed and retaining these structural features.

In particular, ligand binding function is believed to be localized to the extracellular domain, particularly the LBR's, and the soluble forms will preferably retain this particular function. Soluble fragments of PDGF receptors will be useful in substituting for or for interfering with, e.g., blocking, by competing for PDGF binding, the functions of the natural receptor both in vitro and in vivo. Alternatively, soluble forms may interfere with the dimerization of PDGF receptor polypeptides, since the proteins may normally be in, or function in, a dimer form. Receptor dimerization may be essential for proper physiological signal transduction, and introduction of fragments may function to interrupt these processes by blocking their dimerization.

PDGF receptor polypeptides may be purified using techniques of classical protein chemistry, see, e.g., Deutscher (ed.) (1990) Guide to Purification; Methods in Enzymology, Vol. 182, which is hereby incorporated herein by reference. Alternatively, a lectin affinity chromatography step may be used, or a highly specific ligand affinity chromatography

procedure, e.g., one that utilizes a PDGF conjugated to biotin through cysteine residues of the protein mitogen. Purified PDGF receptor polypeptides may also be obtained by a method such as PDGF affinity chromatography using activated CH-Sepharose coupled to PDGF through primary amino groups as described in Imamura et al. (1988) Biochem. Biophys. Res. Commun. 155:583-590.

Depending on the availability of specific antibodies, specific PDGF receptor peptide constructs may also be purified using immuno-affinity chromatography. Antibodies prepared, as described below, may be immobilized to an inert substance to generate a highly specific immuno-affinity column. See, e.g., Harlow and Lane (1990) Monoclonal Antibodies: A Laboratory Manual, Cold Spring Harbor Laboratory, which is hereby incorporated herein by reference.

Various cells or tissues may be selected as starting materials, usually selected on the basis of abundant expression of the desired receptor construct or polypeptide. High expression promoter sequences may be operably linked to a recombinant sequence, preferably an inducible promoter. The promoter is operably linked when it operates to promote the sequence. Appropriate cells that contain relatively large amounts of the receptor protein, as determined by high affinity binding of PDGF, can be transformed with variants of the PDGF receptor polypeptides. These may be used to replace the natural form of PDGF receptor by a construct with a deletion or insertion.

The ligand binding regions (LBR's) or other segments may be "swapped" between different new fusion constructs or fragments. Thus, new chimeric polypeptides exhibiting new combinations of segments can result from the structural linkage of different functional domains. Ligand binding regions which confer desired or modified specificities may be combined with other domains which have another function, e.g., each Ig-like domain could be substituted by a similar domain from other related polypeptides, or LBR's between different alleles or similar receptors may be combined.

The present invention also provides for fusion polypeptides between the receptor polypeptide domains and other homologous or heterologous proteins. Homologous proteins may be fusions between similar but different growth factor receptors resulting in, e.g., a hybrid protein exhibiting ligand specificity of one receptor with an intracellular domain of another, or a receptor which may have altered affinity or a broadened or narrowed specificity of binding. Likewise, heterologous fusions may be constructed which exhibit a combination of properties or activities of the derivative proteins. Typical examples are fusions of a reporter polypeptide, e.g., luciferase, with a domain of a receptor, e.g., a ligand binding domain from the extracellular region of a human platelet-derived growth factor receptor, so that the presence or location of a desired ligand may be easily determined. See, e.g., Dull et al., U.S. Patent No. 4,859,609, which is hereby incorporated herein by reference. Other gene fusion partners include bacterial β-galactosidase, trpE, protein A, β-lactamase, α-amylase, alcohol dehydrogenase, and yeast α-mating factor. See, e.g., Godowski et al., (1988) Science 241: 812-816. Additional sequences with various defined functions may be found by searching through the GenBank™ (National Institutes of Health) sequence data bank. A heterologous fusion protein is one which includes sequences not naturally found in conjunction with one another. Thus, a heterologous fusion protein may be a fusion of two similar, and homologous, sequences.

Fusion proteins would typically be made by either recombinant nucleic acid methods with expression, or by synthetic polypeptide methods. Techniques for nucleic acid manipulation are described generally, for example, in Sambrook et al. (1989) Molecular Cloning: A Laboratory Manual (2nd ed.) volumes 1-3, Cold Spring Harbor Laboratory, which is hereby incorporated herein by reference. Techniques for synthesis of polypeptides are described, for example in Merrifield (1963) J. Amer. Chem. Soc. 85:2149-2456; Atherton et al. (1989) Solid Phase Peptide Synthesis: A Practical Approach, IRL Press,

Oxford; and Merrifield (1986) Science 232:341-347; each of which is hereby incorporated herein by reference.

The recombinant nucleic acid sequences used to produce fusion proteins of the present invention may be derived from natural or synthetic sequences. Many natural gene sequences are available from various cDNA or from genomic libraries using appropriate probes, see, e.g., GenBank™, National Institutes of Health.

Typical probes for isolating platelet-derived growth factor receptor genes may be selected from sequences of Tables 1 and 2, in accordance with standard procedures. Suitable synthetic DNA fragments may be prepared, e.g., by the phosphoramidite method described by Beaucage and Carruthers (1981) Tetra. Letts. 22:1859-1862. A double stranded fragment may then be obtained by either synthesizing the complementary strand and hybridizing the strands together under appropriate conditions or by adding the complementary strand using DNA polymerase with an appropriate primer sequence.

III. Nucleic Acids

The present invention provides nucleic acid sequences encoding various PDGF receptor sequences described above. Tables 1 and 2, respectively set forth the corresponding cDNA sequences encoding human type B and type A PDGF receptor polypeptides.

Substantial homology in the nucleic acid context means either that the segments, or their complementary strands, when compared, are the same when properly aligned, with appropriate nucleotide insertions or deletions, in at least about 60% of the residues, typically at least about 70%, more typically at least about 80%, usually at least about 90%, and more usually at least about 95 to 98% of the nucleotides. Appropriate nucleotide insertions or deletions include interdomain sequences, or those external to the cysteines within a domain, but the sequences within the paired cysteines (or their equivalents in the D4 domains) will often be very important to retain. Structural homology will exist when there is at least about 55% homology over a stretch of at least about

14 nucleotides, typically at least about 65%, more typically at least about 75%, usually at least about 90%, and more usually at least about 95% or more.

Alternatively, substantial homology exists when the segments will hybridize under selective hybridization conditions, to a strand, or its complement, typically using a sequence of at least about 20 contiguous nucleotides derived from Table 1 or 2. However, larger segments would usually be preferred, e.g., at least about 30 contiguous nucleotides, more usually at least about 40, and preferably more than about 50. Selectivity of hybridization exists when hybridization occurs which is more selective than total lack of specificity. See, Kanehisa (1984) Nucleic Acids Res. 12:203-213, which is incorporated herein by reference.

Stringent hybridization conditions will normally include salt concentrations of less than about 1 M, typically less than about 700 mM, more typically less than about 500 mM, usually less than about 400 mM, more usually less than about 300 mM, and preferably less than about 200 mM. Temperature conditions will typically be greater than about 20°C, more typically greater than about 25°C, usually greater than about 30°C, more usually greater than about 37°C, and preferably in excess of about 40°C, depending upon the particular application. As other factors may significantly affect the stringency of hybridization, including, among others, base composition and size of the complementary strands, presence of organic solvents, and extent of base mismatching, the combination of parameters is more important than the absolute measure of any one.

Probes may be prepared based on the sequence of the PDGF receptor encoding sequences provided in Tables 1 and 2. The probes may be used to isolate other PDGF receptor nucleic acid sequences by standard methods. See, e.g., Sambrook et al. (1989) Molecular Cloning: A Laboratory Manual, vols. 1-3, CSH Press, N.Y., which is hereby incorporated herein by reference. Other similar nucleic acids may be selected for by using homologous nucleic acids. Alternatively, nucleic acids encoding these same or similar receptor polypeptides may be

synthesized or selected by making use of the redundancy in the genetic code. Various codon substitutions may be introduced, e.g., silent changes thereby providing various convenient restriction sites, or to optimize expression for a particular system, e.g., to match the optimum codon usage. Mutations may be introduced to modify the properties of the receptors, perhaps to change the ligand binding affinities, the inter-chain affinities, or the polypeptide degradation or turnover rate.

The DNA compositions of this invention may be derived from genomic DNA or cDNA, prepared by synthesis or may be a hybrid of the various combinations. Recombinant nucleic acids comprising sequences otherwise not naturally occurring in continuity are also provided by this invention. An isolated DNA sequence includes any sequence that has been obtained by primer or hybridization reactions or subjected to treatment with restriction enzymes or the like.

Synthetic oligonucleotides can be formulated by the triester method according to Matteucci et al. (1981) J. Am. Chem. Soc. 103:3185 or by other methods such as commercial automated oligonucleotide synthesizers. Oligonucleotides can be labeled by excess polynucleotide kinase (e.g., about 10 units to 0.1 nanomole substrate is used in connection with 50 mM Tris, pH 7.6, 5 mM dithiothreitol, 10 mM $MgCl_2$, 1-2 mM ATP, 1.7 pmoles ^{32}P-ATP (2.9 mCi/mmole) 0.1 mM spermidine, 0.1 mM EDTA). Probes may also be prepared by nick translation, Klenow fill-in reaction, or other methods known in the art. See, e.g., Sambrook et al.

cDNA or genomic libraries of various types may be screened for new alleles or related sequences. The choice of cDNA libraries normally corresponds to a tissue source which is abundant in mRNA for the desired receptors. Phage libraries are normally preferred, but plasmid libraries may also be used. Clones of a library are spread onto plates, transferred to a substrate for screening, denatured, and probed for the presence of desired sequences.

For example, with a plaque hybridization procedure, each plate containing bacteriophage plaques is replicated onto

duplicate nitrocellulose filter papers (Millipore-HATF). The phage DNA is denatured with a buffer such as 500 mM NaOH, 1.5 M NaCl for about 1 minute, and neutralized with, e.g., 0.5 M Tris-HCl, pH 7.5, 1.5 M NaCl (3 times for 10 minutes each). The filters are then washed. After drying, the filters are typically baked, e.g., for 2 hours at 80°C in a vacuum oven. The duplicate filters are prehybridized at 42°C for 4-24 hours with 10 ml per filter of DNA hybridization buffer (20-50% formamide, 5X SSC, pH 7.0, 5X Denhardt's solution (polyvinylpyrrolidone, plus Ficoll and bovine serum albumin; 1X = 0.02% of each), 50 mM sodium phosphate buffer at pH 7.0, 0.2% SDS, and 50 μg/ml denatured salmon sperm DNA). Hybridization with an appropriate probe may be performed at 42°C for 16 hrs with 10 ml/filter of 1 x 10^6 cpm/ml of DNA hybridization buffer containing radioactively labeled probe. The final concentration of formamide is varied according to the length of the probe and the degree of stringency desired. See, e.g., Wetmur and Davidson (1968) J. Mol. Biol. 31:349-370; and M. Kanehisa (1984) Nuc. Acids Res. 12:203-213, each of which is incorporated herein by reference, for a discussion of hybridization conditions and sequence homology.

An oligonucleotide probe based on the disclosed amino acid sequences may be used to site specifically mutate or generate recombinant fusion or deletion constructs. See, e.g., Tables 11 and 12 for preferred oligonucleotide reagents. Procedures such as those described by Kimbel et al. (1987) Methods in Enzymology 154:367, may be used. The sequences PΔ1 through PΔ9 correspond to Seq. ID No. 6 through 14, respectively, and sequences PΔ101 through PΔ109 correspond to Seq. ID No. 15 through 23, respectively.

In accordance with this invention any isolated DNA sequence which encodes substantially a PDGF-R complete structural sequence can be used as a probe. Alternatively, any DNA sequence that encodes a PDGF-R hydrophobic signal sequence and its translational start site may be used. An isolated partial DNA sequence which substantially encodes intact domains exhibiting PDGF-R activity (e.g., ligand or PDGF-R binding) is also part of this invention. Preferred probes are cDNA clones of PDGF receptor polypeptides.

The DNA sequences used in this invention will usually comprise intact domain structures, typically at least about 5 codons (15 nucleotides), more typically at least about 9 codons, usually at least about 13 codons, more usually at least about 18 codons, preferably at least about 25 codons and more preferably at least about 35 codons. One or more introns may also be present. This number of nucleotides is usually about the minimal length required for a successful probe that would hybridize specifically with a PDGF receptor sequence. For example, epitopes characteristic of a PDGF-R may be encoded in short peptides. Usually the wild-type sequence will be employed, in some instances one or more mutations may be introduced, such as deletions, substitutions, insertions, or inversions. These modifications may result in changes in the amino acid sequence, provide silent mutations, modify a restriction site, or provide specific mutations. The genomic sequence will usually not exceed about 200 kb, more usually not exceed about 100 kb, preferably not greater than about 0.5 kb.

Portions of the DNA sequence having at least about 10 nucleotides from a DNA sequence encoding an PDGF receptor peptide will typically be used, more typically at least about 15 nucleotides, usually at least about 20 nucleotides, more usually at least about 25 nucleotides, and preferably at least about 30 nucleotides. The probes will typically be less than about 6 kb, usually fewer than about 3.0 kb, and preferably less than about 1 kb. The probes may also be used to determine whether mRNA encoding a specific PDGF-R is present in a cell or different tissues.

The natural or synthetic DNA fragments coding for a desired platelet-derived growth factor receptor fragment will usually be incorporated into DNA constructs capable of introduction to and expression in an in vitro cell culture. Often the DNA constructs will be suitable for replication in a unicellular host, such as yeast or bacteria, but may also be intended for introduction to, with and without integration within the genome, cultured mammalian, or plant or other eukaryotic cell lines. Human cells may be preferred hosts. Higher eukaryote host cells will often be preferred because their glycosylation and protein processing patterns more likely simulate human processing. DNA constructs prepared for introduction into bacteria or yeast will typically include a replication system recognized by the host, the intended DNA fragment encoding the desired receptor polypeptide construct, transcriptional and translational initiation regulatory sequences operably linked to the polypeptide encoding segment, and transcriptional and translational termination regulatory sequences operably linked to the polypeptide encoding segment. The transcriptional regulatory sequences will typically include a heterologous enhancer or promoter which is recognized by the host. The selection of an appropriate promoter will depend upon the host, but promoters such as the trp, lac, and phage promoters, tRNA promoters, and glycolytic enzyme promoters are known and available. See, e.g., Sambrook et al. (1989). Conveniently available expression vectors which include the replication system and transcriptional and translational regulatory sequences together with the insertion site for the platelet-derived growth factor receptor DNA sequence may be employed. Examples of workable combinations of cell lines and expression vectors are described, e.g., in Sambrook et al. (1989); see also, Metzger et al. (1988) Nature 334:31-36.

Expression vectors for these cells can include expression control sequences, such as an origin of replication, a promoter, an enhancer and necessary processing information sites, e.g., ribosome-binding sites, RNA splice sites, polyadenylation sites, and transcriptional terminator sequences. Preferably, the enhancers or promoters will be

those naturally associated with genes encoding the PDGF receptor polypeptides, although it will be understood that in many cases others will be equally or more appropriate. Other preferred expression control sequences are enhancers or promoters derived from viruses, such as SV40, Adenovirus, Bovine Papilloma Virus, and the like.

Similarly, preferred promoters are those found naturally in immunoglobulin-producing cells, see, e.g., U.S. Patent No. 4,663,281, which is incorporated herein by reference, but SV40, polyoma virus, cytomegalovirus (human or murine) and the LTR from various retroviruses, e.g., murine leukemia virus, murine or Rous sarcoma virus and HIV, may be utilized, as well as promoters endogenous to PDGF-R genes. See, Enhancers and Eukaryotic Gene Expression, (1983) Cold Spring Harbor Press, N.Y., which is incorporated herein by reference.

The vectors containing the DNA segments of interest, e.g., a PDGF receptor polypeptide gene or cDNA sequence, can be transferred into the host cell by well-known methods, which vary depending on the type of cellular host. For example, calcium chloride transfection is commonly utilized for prokaryotic cells, whereas calcium phosphate treatment may be used for other cellular hosts. See generally, Sambrook et al. (1989) Molecular Cloning: A Laboratory Manual (2d ed.) CSH Press, which is incorporated herein by reference. The term "transformed cell" is meant to also include the progeny of a transformed cell.

As with the purified polypeptides, the nucleic acid segments associated with the ligand-binding segment, the extracellular domain and the intracellular domain are particularly useful. These gene segments will be used as probes for screening for new genes exhibiting similar biological activities, though the controlling elements of these genes may also be of importance.

IV. Methods for Making PDGF Receptor Polypeptide Constructs

DNA sequences may also be used to express PDGF-R polypeptides. For example, a DNA sequence of from about 21 nucleotides (encoding about 7 amino acids) to about 2.1 kb (about 700 amino acids) may be used to express a polypeptide having a PDGF receptor specific activity, typically ligand-binding. In particular, constructs retaining the ligand binding regions will be useful, as these constructs will possess binding activity.

In particular, various synthetic linkers and probes may be constructed to facilitate genetic engineering of the PDGF-R nucleic acid sequences. Polymerase chain reaction (PCR) techniques can be applied to producing large quantities of fragments or segments useful in the proper manipulation of the sequences encoding the constructs. See, e.g., Innis et al. (1990) PCR Protocols, Academic Press. Alternatively, nucleic acid synthesizers can produce sufficiently large quantities of fragments for hybridizing to any preselected sequence, e.g., from Table 1 or 2, or for manipulating the sequence to add or delete specific domains or segments. Particularly important segments will be the LBR's.

Large quantities of the receptor proteins may be prepared by expressing the whole receptor or parts of the receptor contained in the expression vehicles in compatible hosts such as E. coli, yeast, mammalian cells, insect cells, or frog oocytes. The expression vehicles may be introduced into the cells using methods well known in the art such as calcium phosphate precipitation (discussed below), lipofectin electroporation, or DEAE dextran transformation.

Usually the mammalian cell hosts will be immortalized cell lines. To study the characteristics of a PDGF-R and its corresponding ligand, it will be useful to transfect, or transform mammalian cells which lack or have low levels of a PDGF receptor. Preferably, a signal sequence can serve to direct the peptide to the cell membrane or for secretion. Cells lacking significant amounts of PDGF receptors include Chinese hamster ovary (CHO) cells, most epithelial cell lines, and various human tumor cell lines.

Transformed or transfected cells can be selected which incorporate a DNA sequence which encodes a receptor that is functionally equivalent to a wild-type receptor thereby conferring a PDGF-sensitive mitogenic response. Such cells will enable the analysis of the binding properties of various added PDGF receptor polypeptides. Transfected cells may also be used to evaluate the effectiveness of a composition or drug as a PDGF antagonist or agonist. The level of receptor tyrosine kinase activity or the rate of nucleic acid synthesis can be determined by contacting transfected cells with drugs or ligands and comparing the effects of various ligand analogues against the controls. Although the most common procaryote cells used as hosts are strains of E. coli, other prokaryotes such as Bacillus subtilis or Pseudomonas may also be used. The DNA sequences of the present invention, including fragments or portions of the sequence encoding for receptor polypeptides comprising intact structural domains, a portion of the receptor, or a polypeptide having an PDGF-R activity, can be used to prepare an expression vehicle or construct for a PDGF-R polypeptide or polypeptide having a PDGF-R activity. Usually the control sequence will be a eukaryotic promoter for expression in a mammalian cell. In some vehicles the receptor's own control sequences may also be used. A common prokaryotic plasmid vector for transforming E. coli is pBR322 or its derivatives, e.g. the plasmid pkt279 (Clontech), see Bolavar et al. (1977) Gene, 2:95. The prokaryotic vectors may also contain prokaryotic promoters for transcription initiation, optionally with an operator. Examples of most commonly used prokaryotic promoters include the beta-lactamase (penicillinase); lactose (lac) promoter, see Cheng et al. (1977) Nature, 198:1056; tryptophan promoter (trp), see Goeddell et al. (1980) Nucleic Acid Res., 8: 457); P_L promoter; and the N-gene ribosome binding site, see Shimatake et al. (1981) Nature, 292:128-; each of which is hereby incorporated herein by reference.

Promoters used in conjunction with yeast can be promoters derived from the enolase gene, see Holland et al. (1981) J. Biol. Chem., 256:1385 ; or the promoter for the

synthesis of glycolytic enzymes such as 3-phosphoglycerate kinase, see Hitzeman et al. (1980) J. Biol. Chem., 255:.

Appropriate non-native mammalian promoters will include the early and late promoters from SV40, see Fiers et al. (1978) Nature, 273:113; or promoters derived from murine muloney leukemia virus, mouse mammary tumor virus, avian sarcoma viruses, adenovirus II, bovine papilloma virus, or polyoma. In addition, the construct may be joined to an amplifiable gene, e.g. dihydrofolate reductase (DHFR) so that multiple copies of the PDGF receptor gene may be made. See, e.g., Kaufman et al. (1985) Mol. and Cell. Biol. 5:1750-1759; and Levinson et al. EPO publication nos. 0117059 and 0117060, each of which is incorporated hereby by reference.

Prokaryotes may be transformed by various methods, including using $CaCl_2$, see Cohen (1972) Proc. Nat'l Acad. Sci. USA, 69:2110; or the RbCl method, see Maniatis et al. (1982) Molecular Cloning: A Laboratory Manual, Cold Spring Harbor Press. Yeast may be transformed, e.g., using a method described by Van Solingen et al. (1977) J. Bacteriol. 130:946; or Hsiao et al. (1979) Proc. Nat'l Acad. Sci. USA 76:3829. With respect to eukaryotes, mammalian cells may be transfected using a calcium phosphate precipitation method, see, e.g., Graham and van der Eb (1978) Virology, 52:546; or by lipofectin (BRL) or retroviral infection, see, e.g., Gilboa (1983) Experimental Manipulation of Gene Expression, Chap. 9, Academic Press P. 175. The actual expression vectors containing appropriate sequences may be prepared according to standard techniques involving ligation and restriction enzymes. See e.g., Maniatis supra. Commercially available restriction enzymes for cleaving specific sites of DNA may be obtained from New England BioLabs, Beverly, Massachusetts.

Particular cotransformations with other genes may be particularly useful. For example, it may be desired to co-express the nucleic acid with another processing enzyme. Such enzymes include signal peptidase, tertiary conformation conferring enzymes, or glycosylating enzymes. This expression method may provide processing functions which otherwise might be lacking in the expression host, e.g., mammalian-like

glycosylation in a prokaryote expression system. Alternatively, the host cell selected for expression may be chosen on the basis of the natural expression of those processing enzymes.

Cell clones are selected by using markers depending on the mode of the vector construction. The marker may be on the same or a different DNA molecule preferably the same DNA molecule. With mammalian cells the receptor gene itself may be the best marker. In prokaryotic hosts the transformant may be selected by resistance to ampicillin, tetracycline, or other antibiotics. Production of a particular product based on temperature sensitivity or compensation may serve as appropriate markers. Various methods may be used to harvest and purify the PDGF-R receptor protein or peptide fragment. The peptide may be isolated from a lysate of the host. The peptide may be isolated from the cell supernatant if the peptide is secreted. The PDGF-R peptide is then further purified as discussed above using HPLC, electrophoresis, or affinity chromatography, e.g., immuno-affinity or ligand affinity.

Another method which can be used to isolate cDNA clones of PDGF-R related species involves the use of the polymerase chain reaction (PCR). See, e.g., Saiki et al. (1985) Science 230:1350. In this approach two oligonucleotides corresponding to distinct regions of the PDGF-R sequence are synthesized and then used in the PCR reaction, typically to amplify receptor-related mRNA transcripts from an mRNA source. Annealing of the oligonucleotides and PCR reactions are performed under conditions of reduced stringency. The resulting amplified fragments are subcloned, and the resulting recombinant colonies are probed with ^{32}P-labeled full-length PDGF-R cDNA. Clones which hybridize under low but not high stringency conditions represent PDGF-R related mRNA transcripts. This approach can also be used to isolate variant PDGF-R cDNA species which arise as a result of alternative splicing, see Frohman et al. (1988) Proc. Nat'l Acad. Sci. USA, 85:8998.

V. Antibodies

Polyclonal and/or monoclonal antibodies to the various PDGF receptor constructs, receptor peptides, and peptide fragments may also be prepared. Peptide fragments may be prepared synthetically in a peptide synthesizer and coupled to a carrier molecule (i.e., keyhole limpet hemocyanin) and injected into rabbits over several months. The rabbit sera is tested for immunoreactivity to the PDGF receptor protein or fragment. Monoclonal antibodies may be made by injecting mice with PDGF-R protein, PDGF-R polypeptides, or mouse cells expressing high levels of the cloned PDGF receptor on its cell surface. Monoclonal antibodies will be screened by ELISA and tested for specific immunoreactivity with the PDGF receptor protein or polypeptides thereof. See, Harlow and Lane (1988) Antibodies: A Laboratory Manual, CSHarbor Press, which is hereby incorporated herein by reference. These antibodies will be useful in assays as well as pharmaceuticals.

Once a sufficient quantity of the desired PDGF receptor polypeptide construct has been obtained, the protein may be used for various purposes. A typical use is the production of antibodies specific for binding to epitopes characteristic of these receptors. These antibodies may be either polyclonal or monoclonal and may be produced by in vitro or in vivo techniques.

For production of polyclonal antibodies, an appropriate target immune system is selected, typically a mouse or rabbit. The substantially purified antigen is presented to the immune system in a fashion determined by methods appropriate for the animal and other parameters well known to immunologists. Typical sites for injection are in the footpads, intramuscularly, intraperitoneally, or intradermally. Of course, another species may be substituted for a mouse or rabbit, typically a mammal, but possibly a bird or other animal.

An immunological response is usually assayed with an immunoassay. Normally such immunoassays involve some purification of a source of antigen, for example, produced by the same cells and in the same fashion as the antigen was

produced. The immunoassay may be a radioimmunoassay, an enzyme-linked assay (ELISA), a fluorescent assay, or any of many other choices, most of which are functionally equivalent but may exhibit particular advantages under specific conditions.

Monoclonal antibodies with affinities of at least about 10^6 M^{-1} preferably 10^8, 10^{10}, or higher will be made by standard procedures as described, e.g., in Harlow and Lane, (1988) Antibodies: A Laboratory Manual, CSH Press; or Goding, (1986) Monoclonal Antibodies: Principles and Practice (2d ed) Academic Press, New York, which are hereby incorporated herein by reference. Briefly, appropriate animals will be selected and the desired immunization protocol followed. After the appropriate period of time, the spleens of such animals are excised and individual spleen cells fused, typically, to immortalized myeloma cells under appropriate selection conditions. Thereafter the cells are clonally separated and the supernatants of each clone are tested for their production of an appropriate antibody specific for the desired region of the antigen.

Other suitable techniques involve in vitro exposure of lymphocytes to the antigenic polypeptides or alternatively to selection of libraries of antibodies in phage or similar vectors. See, Huse et al. "Generation of a Large Combinatorial Library of the Immunoglobulin Repertoire in Phage Lambda," Science 246:1275-1281 (1989), hereby incorporated herein by reference. The polypeptides and antibodies of the present invention may be used with or without modification. Frequently, the polypeptides and antibodies will be labeled by joining, either covalently or non-covalently, a substance which provides for a detectable signal. A wide variety of labels and conjugation techniques are known and are reported extensively in both the scientific and patent literature. Suitable labels include radionuclides, enzymes, substrates, cofactors, inhibitors, fluorescens, chemiluminescers, magnetic particles and the like. Patents, teaching the use of such labels include U.S. Patent Nos. 3,817,837; 3,850,752; 3,939,350; 3,996,345; 4,277,437; 4,275,149; and 4,366,241. Also, recombinant

immunoglobulins may be produced, see Cabilly, U.S. Patent No. 4,816,567.

Antibodies of particular interest are those raised against the ligand binding regions. These will include some antibodies which function as ligands. Or, antibodies may be used to select for compounds which could serve as ligands for modified receptors. See, e.g., Meyer (1990) Nature 347:424-425; and Pain et al. (1990) Nature 347:444-447; each of which is hereby incorporated herein by reference.

VIII. Methods for Use

The present invention provides platelet-derived growth factor receptor (PDGF-R) polypeptide purification methods as well as methods for synthesizing PDGF receptors within cells. Also provided are homogeneous receptors produced by these methods, nucleic acid sequences encoding the receptors or portions of the receptors, as well as expression vehicles containing these sequences, cells comprising the PDGF-receptors, and antibodies to the receptors. In particular, the present invention provides methods for assaying binding and other activities of receptor-like proteins having rearranged combinations of the domains.

The extracellular region of the human type B PDGF receptor protein has been used to successfully bind PDGF BB ligand in a receptor activation assay. PDGF BB ligand binding to NIH3T3 cell-associated PDGF receptors is measured. Ligand binding causes phosphorylation (activation) of the cell associated receptors. Receptor phosphorylation is followed in a multi-step process which first involves solubilization of NIH3T3 cells and separation of cell proteins by electrophoresis of cell extracts on sodium dodecyl sulfate polyacrylamide gels. Gels are blotted onto nitrocellulose and treated with anti-phosphotyrosine monoclonal antibodies to aid in the detection of phosphorylated PDGF receptor. Monoclonal antibodies are visualized through autoradiography of antibody-associated 125-I protein A which has been introduced at the terminal stage of the assay.

If human type B receptor protein (at about a 60 fold molar excess to PDGF BB ligand) is preincubated with ligand for 1 hour prior to incubation with NIH3T3 cells, there is no cell-associated PDGF receptor phosphorylation. This indicates that the human type B PDGF receptor protein binds PDGF BB ligand in solution and prevents the ligand from activating cell-associated PDGF receptors. Thus, polypeptides which contain LBR's may be used to block normal PDGF responses.

The domain containing structures of the present invention will find use both as diagnostic and therapeutic reagents. The receptor polypeptides may be used as affinity reagents for detecting or binding ligand, as well as for interacting with receptor-like proteins, e.g., affecting receptor protein dimerization. The polypeptides will also be useful as reagents for detecting or purifying other proteins which associate with the receptors or fragments thereof.

The receptor polypeptides will also find use in generating other reagents, e.g., antibodies specific for binding epitopes peculiar to the modified receptors. In particular, antibodies raised against newly formed ligand binding determining segments may serve as ligands for the modified receptors. These techniques may provide for separating various functionalities of the receptors, thereby isolating each of the different effector functions from others, in response to PDGF binding.

The modified receptors of the present invention also provide methods for assaying ligands for them. For example, soluble ligand binding fragments will be useful as competing sites for ligand binding, a useful property in a ligand binding assay. In particular, the present invention provides an assay to screen for PDGF binding inhibition, allowing screening of large numbers of compounds. These compounds may be assayed in vitro, which allows testing of cytotoxic or membrane disruptive compounds. The present solid phase system allows reproducible, sensitive, specific, and readily automated assay procedures. Polystyrene 96-well plates may be coated with the appropriate construct with LBR's to assay for ligand binding activity.

Moreover, modifications to the ligand binding domains will lead to binding region combinations with different ligand binding affinities. Thus, modulation of ligand effected response may be easily achieved by inclusion of the appropriate affinity modified analogue.

Solid phase assays using these modified receptors may also be developed, providing greater sensitivity or improved capacity over unmodified binding regions.

Diagnostic kits comprising these reagents are also provided. The kit typically comprise a compartmentalized enclosure, e.g., a plastic substrate having diagnostic reagents of the invention attached thereto. The package will typically also include various buffers, labeling reagents, and other reagents as appropriate for the diagnostic test to be performed. Instructions for use of the related reagents and interpretation of the results will be provided.

In particular, the important functional segment of the extracellular domain will usually be attached to a plastic or other solid phase substrate. The binding regions will usually be selected for a combination of the affinity and ligand binding spectrum of the modified binding segments. Appropriate ligands will often be introduced to determine the ligand binding activity and affinity. Different LBR combinations will be used, and can be used to test for differently modified, e.g., labeled, ligands.

In addition, the peptides will be useful for therapeutic administration. The quantities of reagents necessary for effective therapy will depend upon many different factors, including means of administration, target site, physiological state of the patient, and other medicants administered. Thus, treatment dosages should be titrated to optimize safety and efficacy. Typically, dosages used in vitro may provide useful guidance in the amounts useful for in situ administration of these reagents. Animal testing of effective doses for treatment of particular disorders will provide further predictive indication of human dosage. Various considerations are described, e.g., in Gilman et al. (eds), (1990) Goodman and Gilman's: The Pharmacological Basis of

Therapeutics, 8th ed., Pergamon Press; and Remington's Pharmaceutical Sciences, (1985) 7th ed., Mack Publishing Co., Easton, Penn.; each of which is hereby incorporated by reference. Methods for administration are discussed therein, e.g., for oral, intravenous, intraperitoneal, or intramuscular administration, transdermal diffusion, and others. Pharmaceutically acceptable carriers will include water, saline, buffers, and other compounds described, e.g., in the Merck Index, Merck & Co., Rahway, New Jersey. Because of the high affinity binding between PDGF and its receptors, low dosages of these reagents would be initially expected to be effective. Thus, dosage ranges would ordinarily be expected to be in amounts lower than 1 mM concentrations, typically less than about 10 μM concentrations, usually less than about 100 nM, preferably less than about 10 pM (picomolar), and most preferably less than about 1 fM (femtomolar), with an appropriate carrier.

The pharmaceutical compositions will be administered by parenteral, topical, oral or local administration, such as by aerosol or transdermally, for prophylactic and/or therapeutic treatment. The pharmaceutical compositions can be administered in a variety of unit dosage forms depending upon the method of administration. For example, unit dosage forms suitable for oral administration include powder, tablets, pills, capsules and dragees.

Preferably, the pharmaceutical compositions are administered intravenously. Thus, this invention provides compositions for intravenous administration which comprise a solution of the compound dissolved or suspended in an acceptable carrier, preferably an aqueous carrier. A variety of aqueous carriers may be used, e.g., water, buffered water, 0.4% saline, and the like. These compositions may be sterilized by conventional, well known sterilization techniques, or may be sterile filtered. The resulting aqueous solutions may be packaged for use as is, or lyophilized, the lyophilized preparation being combined with a sterile aqueous solution prior to administration. The compositions may contain pharmaceutically acceptable auxiliary substances as required to

approximate physiological conditions, such as pH adjusting and buffering agents, tonicity adjusting agents, wetting agents and the like, for example, sodium acetate, sodium lactate, sodium chloride, potassium chloride, calcium chloride, sorbitan monolaurate, triethanolamine oleate, etc.

For solid compositions, conventional nontoxic solid carriers may be used which include, for example, pharmaceutical grades of mannitol, lactose, starch, magnesium stearate, sodium saccharin, talcum, cellulose, glucose, sucrose, magnesium carbonate, and the like. For oral administration, a pharmaceutically acceptable nontoxic composition is formed by incorporating any of the normally employed excipients, such as those carriers previously listed, and generally 10-95% of active ingredient, preferably about 20% (see, Remington's, supra).

For aerosol administration, the compounds are preferably supplied in finely divided form along with a surfactant and propellant. The surfactant must, of course, be nontoxic, and preferably soluble in the propellant. Representative of such agents are the esters or partial esters of fatty acids containing from 6 to 22 carbon atoms, such as caproic, octanoic, lauric, palmitic, stearic, linoleic, linolenic, olesteric and oleic acids with an aliphatic polyhydric alcohol or its cyclic anhydride such as, for example, ethylene glycol, glycerol, erythritol, arabitol, mannitol, sorbitol, the hexitol anhydrides derived from sorbitol, and the polyoxyethylene and polyoxypropylene derivatives of these esters. Mixed esters, such as mixed or natural glycerides may be employed. The surfactant may constitute 0.1%-20% by weight of the composition, preferably 0.25-5%. The balance of the composition is ordinarily propellant. Liquefied propellants are typically gases at ambient conditions, and are condensed under pressure. Among suitable liquefied propellants are the lower alkanes containing up to 5 carbons, such as butane and propane; and preferably fluorinated or fluorochlorinated alkanes. Mixtures of the above may also be employed. In producing the aerosol, a container equipped with a suitable valve is filled with the

appropriate propellant, containing the finely divided compounds and surfactant. The ingredients are thus maintained at an elevated pressure until released by action of the valve.

The compositions containing the compounds can be administered for prophylactic and/or therapeutic treatments. In therapeutic applications, compositions are administered to a patient already suffering from a disease, as described above, in an amount sufficient to cure or at least partially arrest the symptoms of the disease and its complications. An amount adequate to accomplish this is defined as "therapeutically effective dose." Amounts effective for this use will depend on the severity of the disease and the weight and general state of the patient.

In prophylactic applications, compositions containing the compounds of the invention are administered to a patient susceptible to or otherwise at risk of a particular disease. Such an amount is defined to be a "prophylactically effective dose." In this use, the precise amounts again depend on the patient's state of health and weight.

The invention will better be understood by reference to the following illustrative examples. The following examples are offered by way of illustration and not by way of limitation.

EXPERIMENTAL

In general, standard techniques of recombinant DNA technology are described in various publications, e.g., Sambrook et al. (1989) Molecular Cloning: A Laboratory Manual, Cold Spring Harbor Laboratory; Ausubel et al. (1987) Current Protocols in Molecular Biology, vols. 1 and 2 and supplements; and Wu and Grossman (eds.) (1987) Methods in Enzymology, Vol. 53 (Recombinant DNA Part D); each of which is incorporated herein by reference.

I. Human Extracellular Region

Equivalent techniques for construction, expression, and determination of the physiological effect of truncation or deletion analogues of the soluble extracellular receptor

fragments from the human receptor may be performed using the nucleic acid, polypeptide, and other reagents provided herein.

A. Type B Segments

Constructs of type B receptor polypeptides were made as follows:

The 3.9 kb EcoRI-Hind III cDNA fragment of the human type B hPDGF-R was subcloned into the EcoRI-Hind III site of M13 Mp18 to produce a vector Mp18PR. For techniques, see Maniatis et al. (1982) Molecular Cloning: A Laboratory Manual, Cold Spring Harbor, N.Y., which is incorporated herein by reference. Verification of subcloning was performed by restriction enzyme digestion analysis and dideoxy chain termination sequencing, as described by Sanger et al. (1977) Proc. Nat'l Acad. Sci. USA 74:5463. Oligonucleotide directed in vitro mutagenesis was performed according to the method described by Kunkel et al. (1987) Methods in Enzymol., 154:367. The strategy for oligonucleotide directed in vitro deletion mutagenesis of Mp18PR is outlined in Fig. 1.

In brief, a series of oligonucleotides were designed to create a nested set of soluble type B hPDGF receptor extracellular regions by deletion mutagenesis. These domains are designated Domain 1 through Domain 5 (D1-D5), suitable for expression in an appropriate eukaryotic expression system. A description of the mutagenic oligonucleotides aligned with the corresponding regions of the human PDGF receptor are listed in Table 10. The resulting constructs are labeled as indicated in Table 13. The antisense strand was used for mutagenesis throughout. Mutagenesis of PΔ1, PΔ2, PΔ3, PΔ4, and PΔ5, utilized Mp18PR as the template and mutagenesis of PΔ6, PΔ7, PΔ8, and PΔ9, utilized MP 18 PΔ1 as the template. PΔ1, a 41 bp oligomer, introduced a TAG stop codon after Lysine$_{499}$ (K_{499}) of D5 and removed the transmembrane (TM) as well as entire intracellular kinase domain (K), producing an Mp18 PΔ1 (see Fig. 1). PΔ1 codes for 530_{aa} 148_{aa} precursor proteins.

pBJPΔ9	

The human PDGF receptor constructs were subsequently subcloned into the EcoRI-Hind III site of pBJ1 a derivation of pCDL-SRα296, as described in Takabe et al. (1988) Molec. Cell Biol. 8:466, and co-transfected with pSV2NEO, as described by Southern and Berg (1982) J. Mol. Appl. Gen., 1: 327, into Chinese hamster ovary cells (CHO). See Figs. 2 and 3.

Function of the constructs was demonstrated as follows:

A sample of 0.33 nM PDGF BB ligand is preincubated for 1 hr at 4°C under the following conditions:

1. a polyclonal antibody to human PDGF (this antibody recognizes human PDGF AA, PDGF BB and PDGF AB);
2. 18 nM (60 fold molar excess to PDGF BB) human type B PDGF receptor;
3. phosphate buffered saline solution that the receptor and antibody are in; or
4. no additions but the ligand itself.

In a duplicate set of experiments, 0.33 nM PDGF AA is incubated with three of the above preincubation conditions, e.g., 2, 3, and 4 above. The human type B PDGF receptor does not appreciably recognize PDGF AA but this ligand will still activate cell-associated human type A PDGF receptor from NIH3T3

cells and so is a control for human type B PDGF receptor specificity and PDGF BB-dependent activation versus non-specific general cellular effect, e.g., cytotoxicity.

The preincubated materials were in a final volume of 0.5 ml. They were placed in one well each of a six well tissue culture dish containing a confluent layer of serum starved (quiescent) NIH3T3 cells which were chilled to 4°C. The cells and incubation mixtures were agitated, e.g., rocked, at 4°C for 2 h. They were then washed twice with 4°C phosphate buffered saline. Forty µl of 125 mM Tris(hydroxymethyl)amino methane (Tris), pH 6.8, 20% (v/v) glycerol, 2% (w/v) sodium dodecyl sulfate (SDS), 2% (v/v) 2-mercaptoethanol, and 0.001% bromphenol blue, (known as SDS sample buffer), was added per microtiter well followed by 40 µl of 100 mM Tris, pH 8.0, 30 mM sodium pyrosphoshate, 50 mM sodium fluoride, 5 mM ethylenediaminetetraacetic acid (EDTA), 5 mM ethylenebis(oxyethylenenitrilio)tetraacetic acid, 1% (w/v) SDS, 100 mM dithiothreitol, 2 mM phenylmethylsulfonylfluoride (PMSF), and 200 µM sodium vanadate was added to the cells. The cells were solubilized and 40 µl additional SDS sample buffer was added to the solubilizate. This material was boiled 5 minutes and loaded onto a single gel sample well of a 7.5% sodium dodecyl sulfate polyacrylamide gel. Cellular proteins were separated by electrophoresis.

The separated proteins were transferred to nitrocellulose by electrotransfer and the resulting "Western blot" was incubated with 3 changes of 0.5% (w/v) sodium chloride, 5 mg/ml bovine serum albumin, 50 mM Tris, pH 7.5, (designated blocking buffer) for 20 minutes each at room temperature. A 1/1000 dilution of PY20 (a commercially available monoclonal antibody to phosphotyrosine [ICN]) in blocking buffer was incubated with the blot overnight at 4°C. The blot was washed 3 times for 20 minutes each at room temperature in blocking buffer. The blot was incubated with 4 µCi/40 ml of ^{125}I-Protein A [Amersham] in blocking buffer for 1 hour at room temperature and washed 3 times for 20 minutes each at room temperature in blocking buffer. The blot was exposed

to X-ray film for 48 h with one intensifying screen at -70°C and developed with standard reagents.

Figure 4 shows the results of the autoradiogram with the conditions mentioned above plus the additional condition of no added ligand (no PDGF). This added condition defines the level of cell-associated receptor activation (e.g., phosphorylation) in the absence of any added ligand. Both the antibody and the human type B PDGF receptor neutralized the activation of cell-associated PDGF receptor by PDGF BB. This is apparently due to direct binding and sequestration of the ligand making it unavailable for PDGF receptor activation. p185 shows the receptor position.

B. Type A Sequence

Similar manipulations using the mutagenic oligonucleotides of Table 12 are used to construct the type A constructs listed in Table 15. Note that the type A constructs have not actually been produced, but would readily be produced by these methods. Similar assays are used to test the function of the constructs.

C. PDGF Plate Assay

Polystyrene microtiter plates (Immulon, Dynatech Laboratories) were coated with the extracellular region fragment of the type B human PDGF receptor (described above) by incubating approximately 10-100 ng of this protein per well in 100 µl of 25 mM Tris, 75 mM NaCl, pH 7.75 for 12 to 18 h at 4°C. The protein was expressed in transfected CHO cells and collected in serum-free media (Gibco MEMα) at a concentration of 0.2 - 1 µg/ml, with a total protein concentration of 150 - 300 µg/ml.

The human PDGF type B receptor extracellular region fragment was concentrated and partially purified by passing the media over wheat germ-agglutinin-sepharose at 4°C (at 48 ml/h) in the presence of 1 mM PMSF. After extensive washing, the protein was eluted in 0.3 M N-acetyl-glucosamine, 25 mM Hepes, 100 mM NaCl, 1 mM PMSF, pH 7.4. This fraction was then applied to Sephacryl S-200 HR (Pharmacia) equilibrated in 0.15 M ammonium bicarbonate pH 7.9. The fractions containing receptor (3 - 10 ng/µl) were detected by SDS-PAGE and Western blotting with a polyclonal rabbit antibody, made by standard methods, against a Domain 1 (D1) segment from the receptor external region. These fractions (3 - 10 ng/µl) were used to coat the microtiter wells as described above. The wells were then drained, rinsed once with 200 µl each of 0.5% gelatin (Bio-Rad, EIA grade), 25 mM Hepes, 100 mM NaCl, pH 7.4, and incubated for 1-2 h at 24°C with 150 µl of this same solution. The wells were drained and rinsed twice with 0.3% gelatin, 25 mM Hepes, 100 mM NaCl, pH 7.4 (150 µl each). 90 µl of the 0.3% gelatin solution was put in each well (wells used to test nonspecific binding received just 80 µl and then 10 µl of 0.01 mg/ml non-labeled PDGF in the 0.3% gelatin solution). PDGF BB (Amgen) was iodinated at 4°C to 52,000 CPM/ng with di-iodo Bolton-Hunter reagent (Amersham) and approximately 40,000 CPM was added per well in 10 µl, containing 0.024% BSA, 0.4% gelatin, 20 mM Hepes, 80 mM NaCl, 70 mM acetic acid, pH 7.4. The plate was incubated for 2-3 h at 24°C, after which wells were washed three times with 150 µl each with 0.3% gelatin, 25 mM Hepes, 100 mM NaCl, pH 7.4. The bound radioactivity remaining was

solubilized from the wells in 200 µl 1% SDS, 0.5% BSA, and counted in a gamma-counter. The nonspecific binding was determined in the presence of a 150-fold excess of unlabeled PDGF BB (Amgen) and was about 7% of the total bound ^{125}I-PDGF.

Similar assays will be possible using type A receptor fragments. However, the type A receptor fragments are more sensitive to the presence of other proteins than the type B fragments, and appear to require a different well coating reagent from the gelatin. Hemoglobin is substituted for gelatin in the buffers at about the same concentrations. Other blocking proteins will be useful selected from, e.g., the Sigma Chemical Company. Titrations to optimize the protein type and concentration will be performed to find proteins which do not affect the receptor protein binding.

The present assays require less than 5 ng/well of receptor soluble form, which was expressed in transfected CHO cells, and partially purified by affinity and gel chromatography. Using iodinated PDGF-BB, the specific binding of less than 10 pg of ligand can be detected in an assay volume of 100 µg/well. At 4°C, the binding of ^{125}I-PDGF BB to immobilized receptor is saturable and of high affinity. The Kd by Scatchard analysis was about 1 nM with 1.8 x 10^{10} sites per well. The nonspecific binding, determined in the presence of a 100-fold excess of cold PDGF BB, was usually only about 5-10% of the total binding. The binding was also specific for the isoform of the ligand, insofar as excess cold PDGF AA did not inhibit ^{125}I-PDGF BB binding. Furthermore, the external region of the type B PDGF receptor in solution competes with its immobilized form for binding iodinated PDGF BB (IC_{50} = 5nM). The ^{125}I-PDGF BB bound after 4 h at 4°C is only slowly dissociable in binding buffer ($t_{1/2}$ > 6 h), but is completely displaced by the addition of a 150-fold excess of unlabeled PDGF BB ($t_{1/2}$ < 1 h).

These studies were made possible by the availability of growth factor preparations devoid of contamination with other growth factors and by the use of a receptor expression system in which all of the measured PDGF responses could be attributed to this single transfected receptor cDNA.

All publications and patent applications herein are incorporated by reference to the same extent as if each individual publication or patent application was specifically and individually indicated to be incorporated by reference. The invention now being fully described, it will be apparent to one of ordinary skill in the art that many changes and modifications can be made thereto without departing from the spirit or scope of the appended claims.

(xi) SEQUENCE DESCRIPTION: SEQ ID NO:23:

AGCCTAATCC TCTGCCAGCT TTCATCCATT CTGGACTTGG TC 42

WHAT IS CLAIMED IS:

1. A platelet-derived growth factor receptor (hPDGF-R) fragment of between about 8 and 400 amino acids comprising one or more platelet-derived growth factor (PDGF) ligand binding regions (LBR's) from extracellular domains D1, D2, or D3, wherein said fragment binds a platelet-derived growth factor ligand.

2. A PDGF-R fragment of Claim 1, wherein said fragment exhibits an affinity of about 5 nM.

3. A PDGF-R fragment of Claim 1, wherein said fragment comprises at least about 15 contiguous amino acids from a domain D3 intra-cysteine region.

4. A PDGF-R fragment of Claim 1, wherein said fragment lacks a transmembrane region.

5. A PDGF-R fragment of Claim 1, wherein said fragment is soluble.

6. A PDGF-R fragment of Claim 1, wherein at least one of said LBR's is a domain D3 LBR.

7. A PDGF-R fragment of Claim 1, wherein at least one of said LBR's is from a type B or type A PDGF-R LBR.

8. A PDGF-R fragment of Claim 1, wherein said fragment is a contiguous sequence within Table 1 or Table 2.

9. A PDGF-R fragment of Claim 1, wherein said fragment is selected from the group of formulae consisting of:

a) Xa-Dm-Xc;

b) Xa-Dm-X1-Dn-Xc;

c) Xa-Dm-X1-Dn-X2-Dp-Xc; and

d) Xa-Dm-X1-Dn-X2-Dp-X3-Dq-Xc;

wherein:

each of Xa, X1, X2, X3, and Xc is, if present, a polypeptide segment lacking a D domain; and

each of Dm, Dn, Dp, and Dq is, independently of one another, selected from the group consisting of D1, D2, D3, D4, and D5.

10. A PDGF-R fragment of Claim 1, wherein said fragment is selected from the group consisting of:

a) D1-D2-D3; and

b) D1-D2-D3-D4.

11. A soluble human platelet-derived growth factor receptor (hPDGF-R) fragment of less than about 400 amino acids comprising at least one platelet-derived growth factor (PDGF) ligand binding region (LBR) from domain D3, wherein said fragment specifically binds to a platelet-derived growth factor ligand.

12. A hPDGF-R fragment of Claim 11, wherein said fragment comprises a sequence of at least about 15 contiguous amino acids from the intra-cysteine portion of domain D3.

13. A hPDGF-R fragment of Claim 11, wherein said fragment is substantially pure.

14. A hPDGF-R fragment of Claim 11, wherein said LBR is derived from a type B or type A PDGF-R, and further is a sequence in Table 1 or Table 2.

15. A nucleic acid sequence encoding a PDGF-R fragment of Claim 1.

16. A nucleic acid sequence encoding a hPDGF-R fragment of Claim 11.

17. A nucleic acid of Claim 15 wherein said encoding sequence is operably linked to a promoter.

18. A cell comprising a PDGF-R fragment of Claim 1.

19. A cell comprising a hPDGF-R fragment of Claim 11.

20. A mammalian cell comprising a nucleic acid of Claim 15.

21. A mammalian cell comprising a nucleic acid of Claim 16.

22. A cell comprising both a nucleic acid of Claim 15, and a protein expression product of said nucleic acid.

23. An antibody which recognizes an epitope of a PDGF-R fragment of Claim 1, wherein said epitope is not found on a natural PDGF-R.

24. An antibody of Claim 23, wherein said antibody is a monoclonal antibody.

25. A method for measuring the PDGF ligand binding activity of a biological sample comprising the steps of:

a) contacting an aliquot of said sample to a PDGF ligand in the presence of a PDGF-R fragment of Claim 1 in a first analysis;

b) contacting an aliquot of said sample to a PDGF ligand in the absence of said PDGF-R fragment in a second analysis; and

c) comparing the amount of said PDGF ligand binding in the two analyses.

26. A method of Claim 25, wherein said PDGF-R fragment is attached to a cell.

27. A method of Claim 26, wherein said PDGF-R fragment is attached to a solid substrate.

28. A method of Claim 27, wherein said solid substrate is a microtiter dish.

29. A method for measuring the PDGF ligand content of a biological sample comprising the steps of:

a) contacting an aliquot of said sample to a ligand binding region (LBR) in the presence of a PDGF-R fragment of Claim 1 in a first analysis;

b) contacting an aliquot of said sample to a LBR in the absence of said PDGF-R fragment in a second analysis; and

c) comparing the amount of binding in the two analyses.

30. A method of Claim 29, wherein said contacting steps are performed simultaneously.

INTERNATIONAL SEARCH REPORT

International Application No. PCT/US92/00730

I. CLASSIFICATION OF SUBJECT MATTER (if several classification symbols apply, indicate all)[3]

According to International Patent Classification (IPC) or to both National Classification and IPC

IPC (5): Please See Attached Sheet.
US CL : 435/2, 4, 6, 240.2; 424/85.8; 536/27; 530/350

II. FIELDS SEARCHED

Minimum Documentation Searched[4]

Classification System	Classification Symbols
U.S.	435/2, 4, 6, 240.2; 424/85.8; 536/27; 530/350

Documentation Searched other than Minimum Documentation to the extent that such Documents are included in the Fields Searched[5]

* Special categories of cited documents:[15]

"A" document defining the general state of the art which is not considered to be of particular relevance
"E" earlier document but published on or after the international filing date
"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
"O" document referring to an oral disclosure, use, exhibition or other means
"P" document published prior to the international filing date but later than the priority date claimed
"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step
"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"&" document member of the same patent family

I. CLASSIFICATION OF SUBJECT MATTER:
IPC (5):

C 07 H 15/12, 17/00; C 07 K 3/00, 13/00, 15/00, 17/00; A 01 N 1/02; C 12 Q 1/00, 1,68; C12 N 5/00

VI. OBSERVATIONS WHERE UNITY OF INVENTION WAS LACKING
This ISA found multiple inventions as follows:

I. Claims 1-22 and 25-28 are, drawn to a method for measuring the PDGF-D ligand by using a platelet-derived growth factor receptor fragment and its DNA sequence.
II. Claims 23-24 are, drawn to an antibody.
III. Claims 29-30 are, drawn to a method for measuring the PDGF ligand content of a biological sample.
